Dengue Fever

What is dengue fever?
Dengue fever is a disease caused by any one of four closely related viruses. Because there are four different viruses, a person can be infected as many as four times, once with each type.

Dengue hemorrhagic fever is a more severe form of dengue fever, caused by the same viruses.

How common is dengue fever?
The disease is common in most tropical and subtropical areas including some islands in the Caribbean, Mexico, most countries of South and Central America, the Pacific, Asia, and parts of tropical Africa. Cases originating in the United States are rare, occurring occasionally in southern Texas. Usually, dengue fever occurs due to a person developing the disease after they have returned from one of these countries where it is common.

How is dengue fever spread?
Dengue fever and dengue hemorrhagic fever are transmitted to people by the bite of an infected mosquito. A mosquito becomes infected with the dengue virus when it bites a person who has dengue fever.

Dengue cannot be spread directly from person to person.

What are the symptoms of dengue fever?
Dengue fever is characterized by the rapid development of a high fever, intense headache, backache, joint pain, loss of appetite, diarrhea, nausea and vomiting, and rash. The rash develops on the feet or legs three to four days after a person develops the fever. Generally, younger children have a milder illness than older children and adults.

Symptoms of dengue hemorrhagic fever include fever lasting two to seven days and other nonspecific signs and symptoms. As the fever begins to subside, the patient may become restless or lethargic, show signs of circulatory failure, and experience hemorrhagic manifestations. These include the tendency to bruise easily, bleeding nose or gums, and possibly internal bleeding. If not treated, the patient could experience shock, circulatory failure, and death.

What is the treatment for dengue fever?
There is no specific treatment or medication for dengue fever. A person who has dengue fever should take a non-aspirin pain reliever, rest, drink plenty of fluids, and see their doctor. Aspirin should be avoided due to the fact that it reduces clotting effects, aggravating bleeding (if it should occur).
Dengue hemorrhagic fever can be treated by intravenous fluids and oxygen therapy if an early diagnosis is made. Hospitalization is frequently required to manage the illness.

**How can dengue fever be prevented?**
There is no vaccine to prevent dengue fever. The best preventive measure is to limit exposure to mosquitoes – using mosquito netting and repellents and wearing long-sleeved shirts and long pants. Mosquito control in areas where dengue is prevalent is also important, eliminating places where mosquitoes lay eggs (primarily in containers that hold water).
